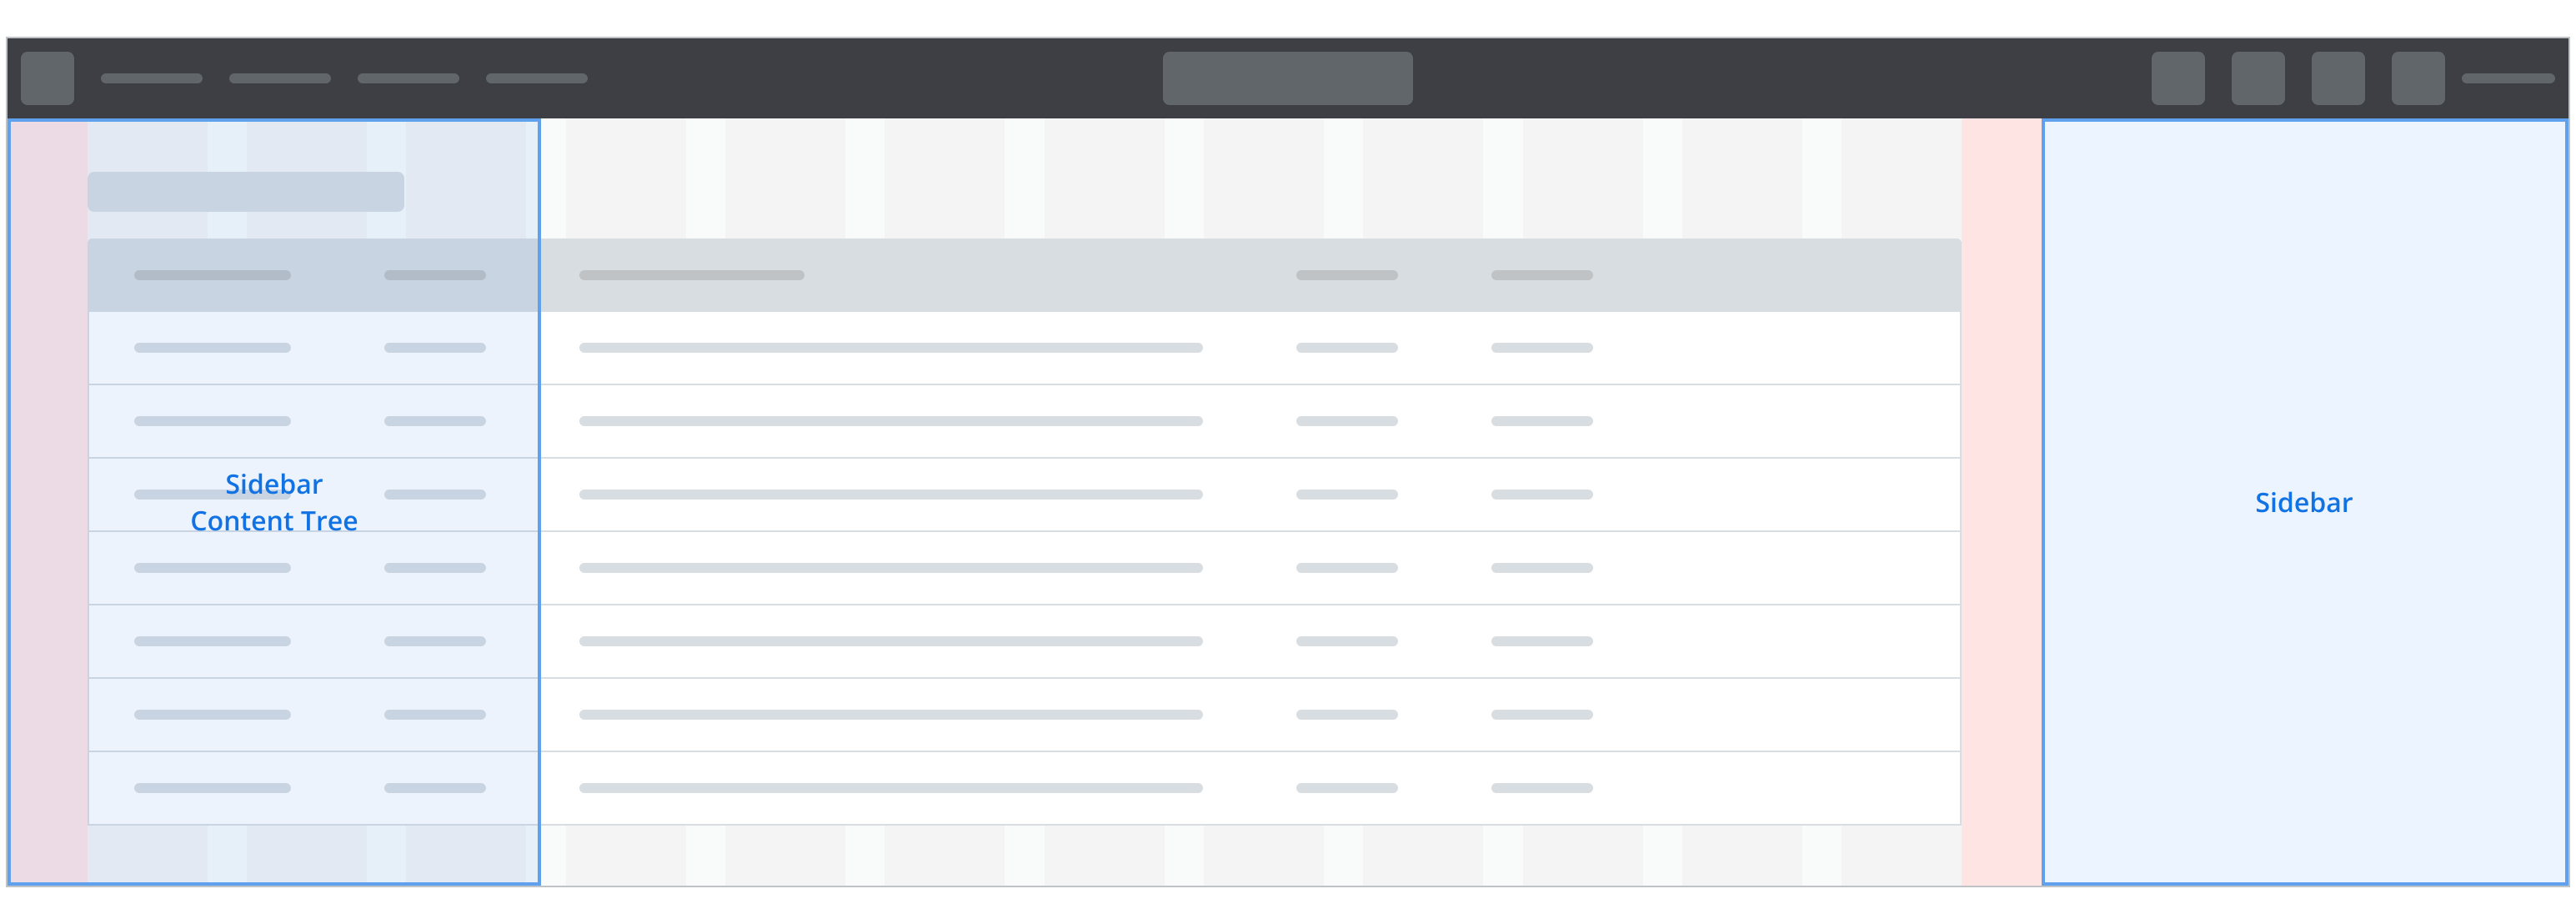
Layout Patterns

The Application Layout defines how the main structural areas of the product behave across screen sizes.
It explains how the header, grid container, and side panels interact with each other.

Layout Structure

The interface is built from three main layers: a full-width sticky header, a responsive grid container for the main content, and optional side panels that appear when the user needs navigation or article-related actions. The header is always present and spans the entire viewport width.

The grid container holds the main content and follows the grid breakpoints. Side panels are structural UI regions and are handled separately from the grid.



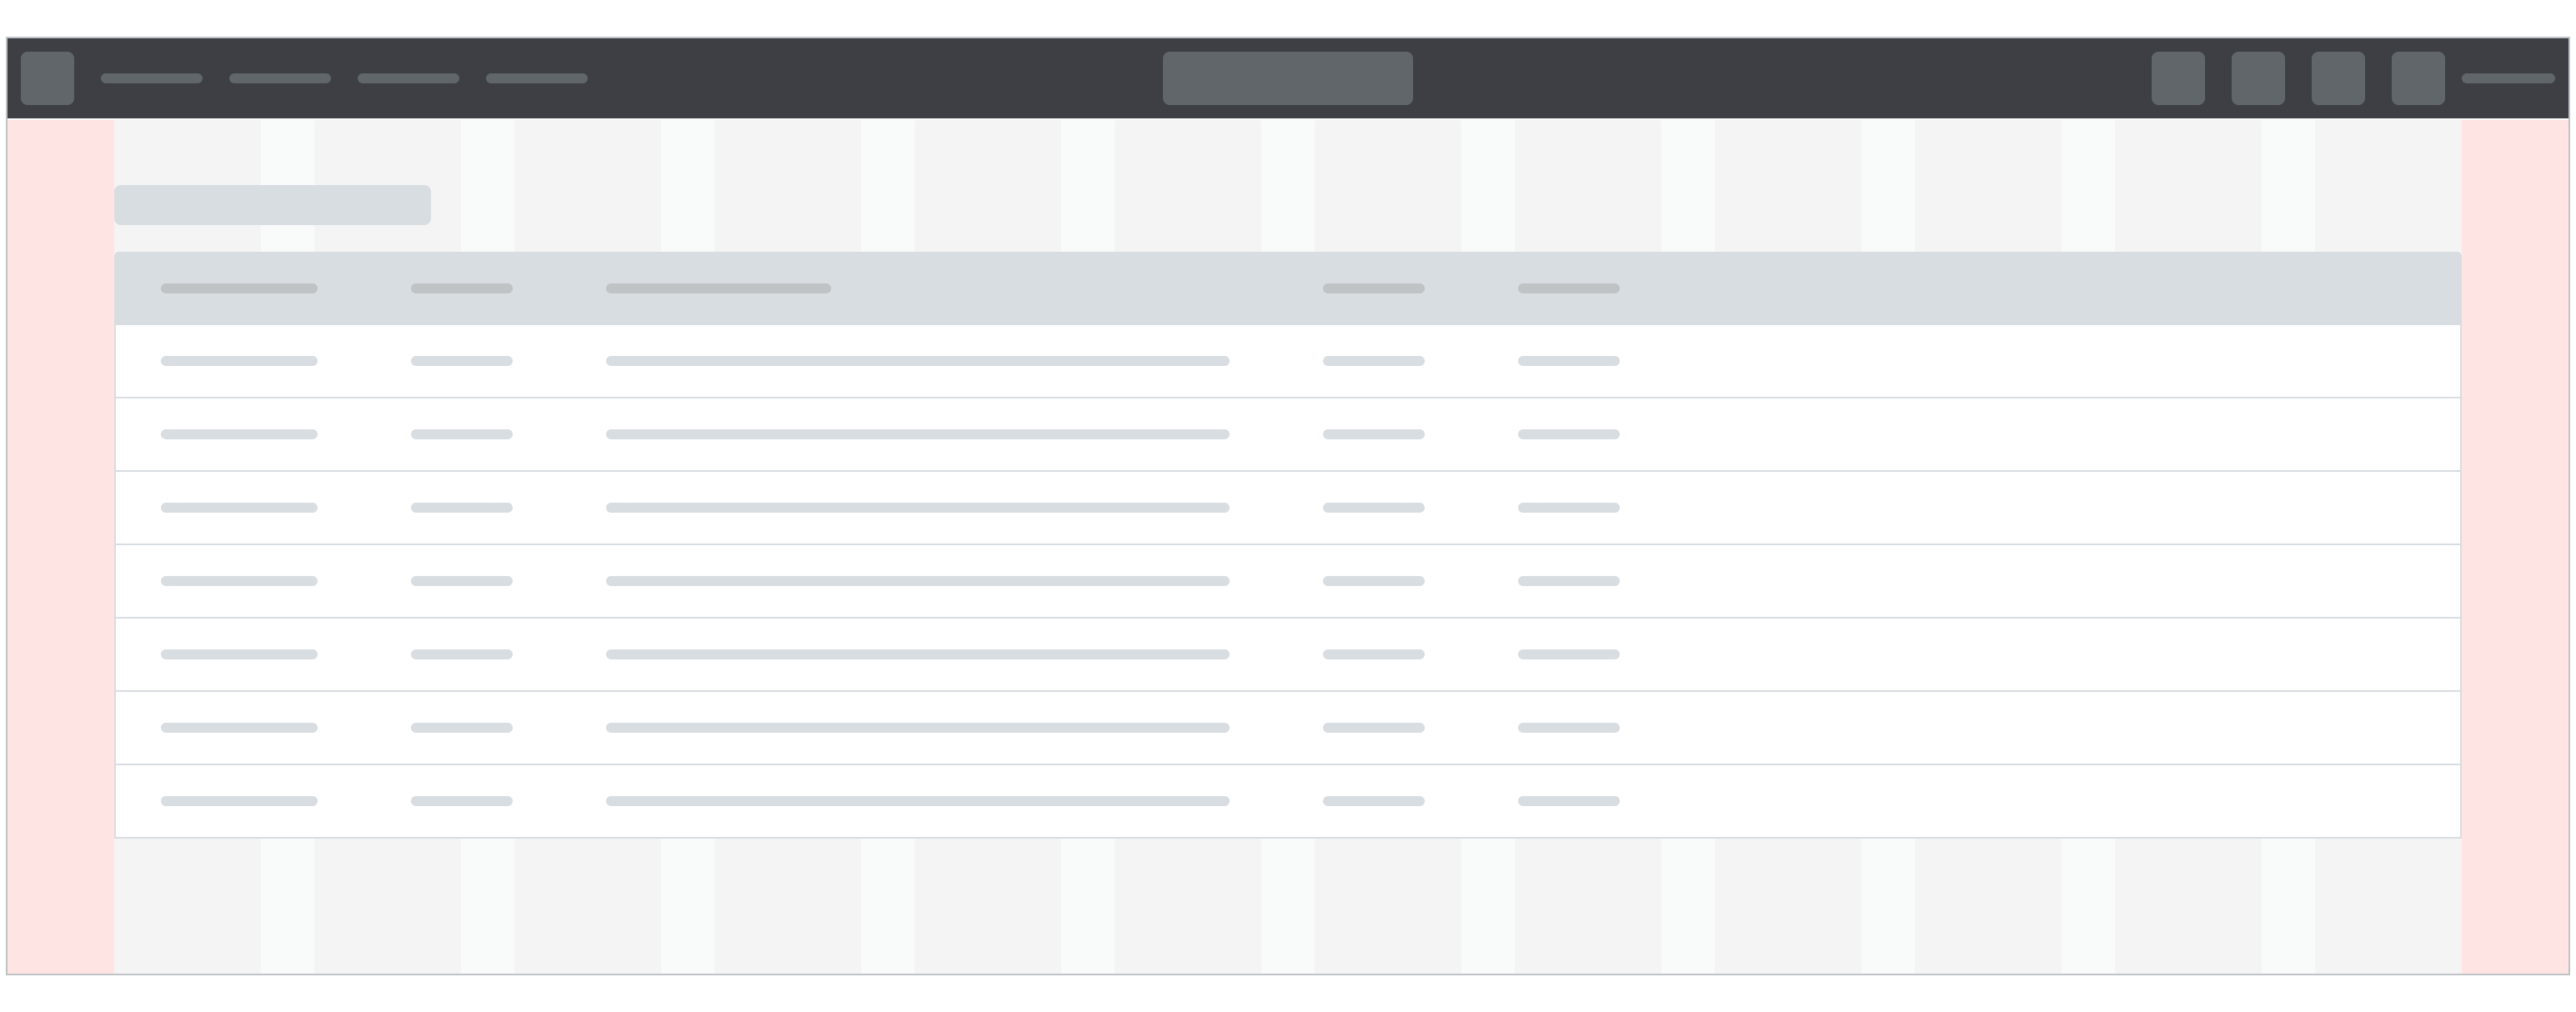
Region	Width	Height
Header	100%	Fixed
Action bar ?	100%	Fixed
Side Panel (Left)	Flexible (235px - 470px)	Flexible
Side Panel (Right)	Mixed (460px, 360px / flexible on XS)	Flexible
Table	Flexible	Flexible

Width Strategy

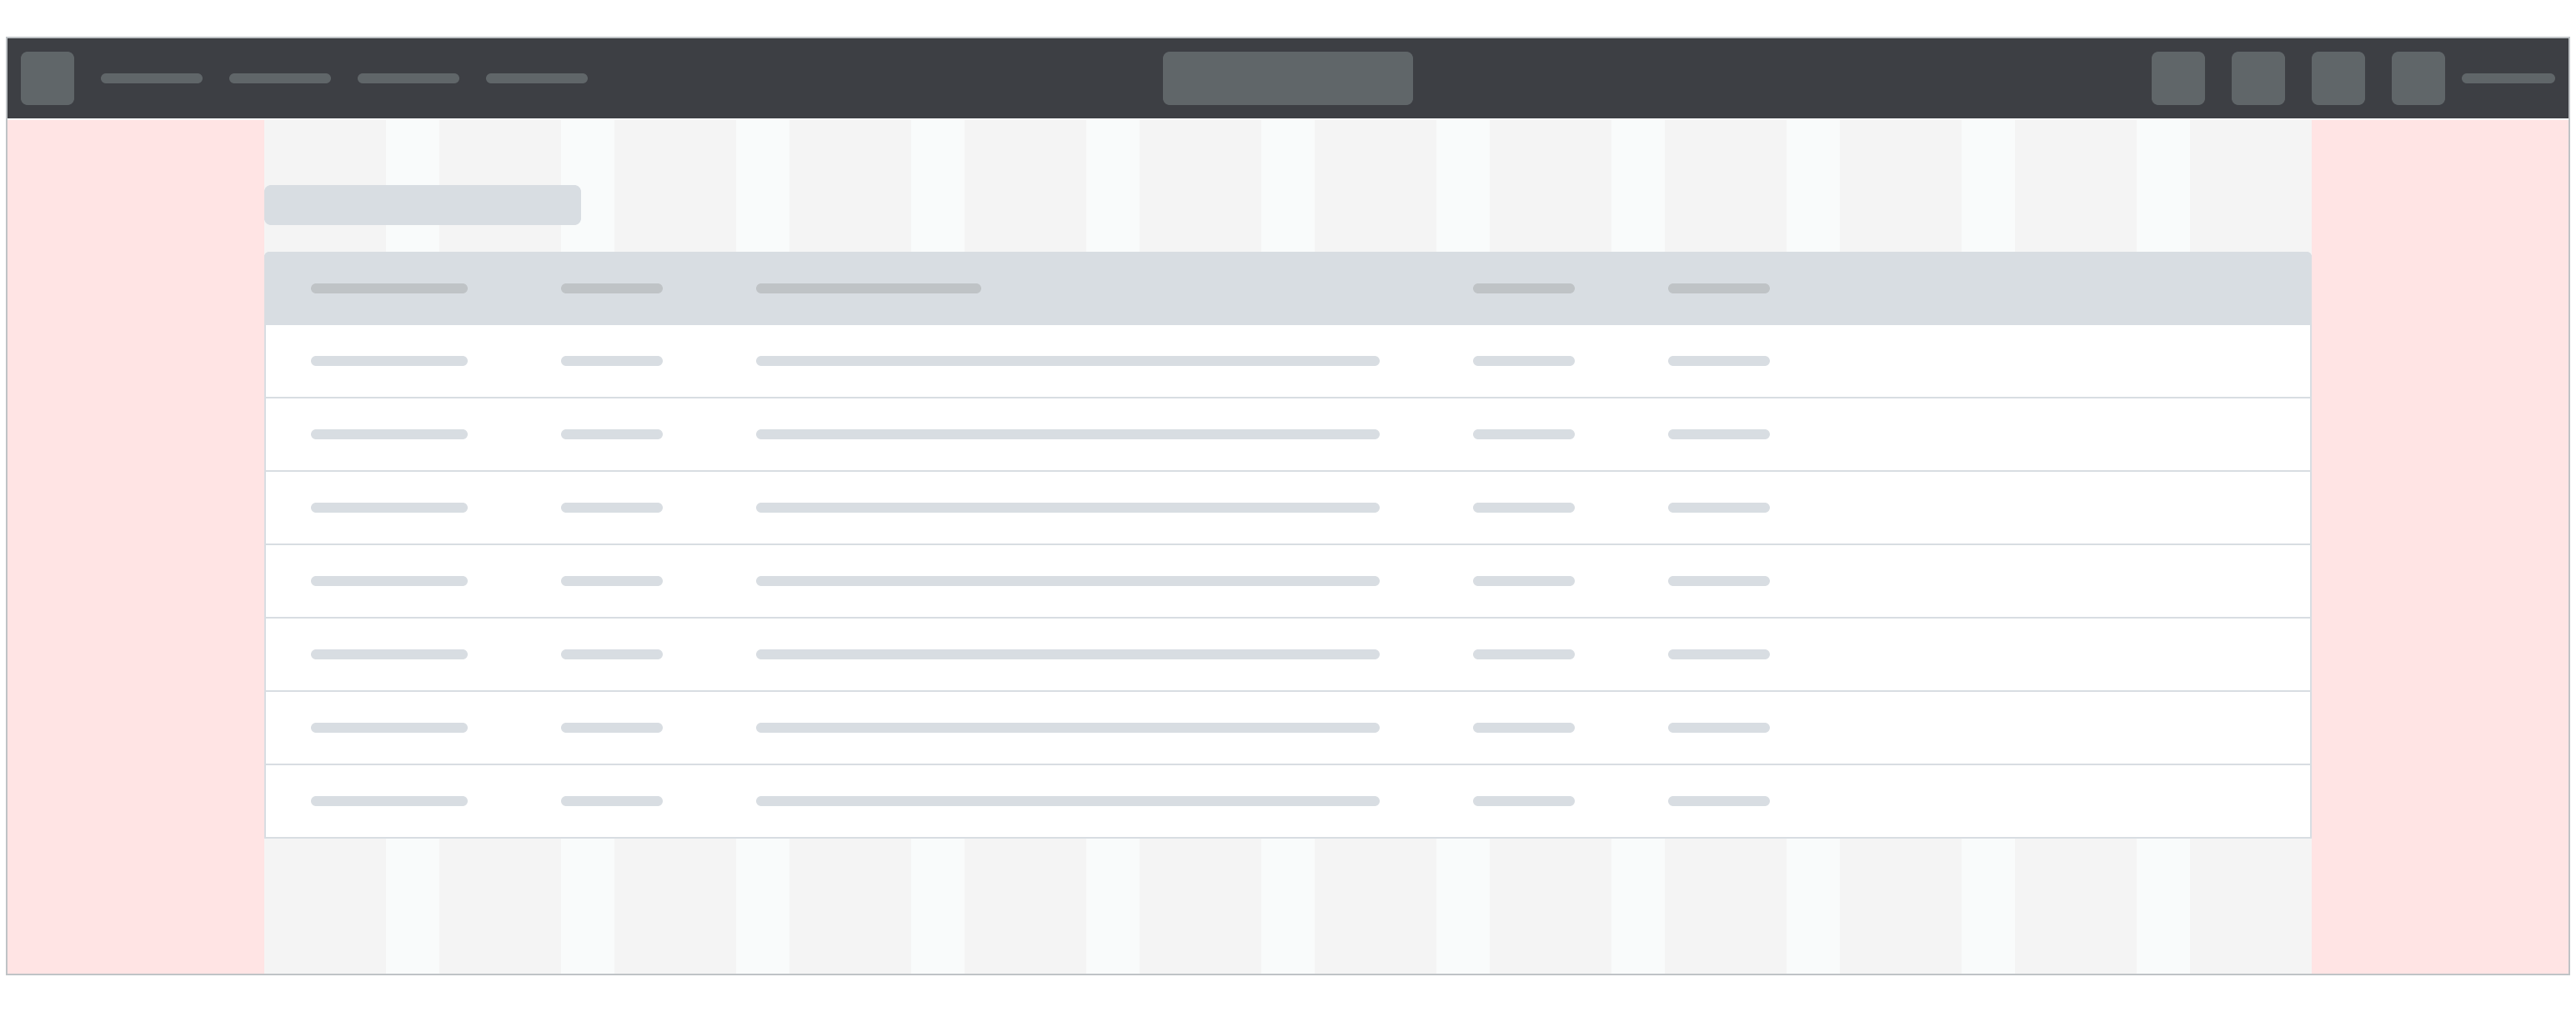
The grid container grows responsively up to 1920px. After 1920px, the grid stops expanding and stays centered on the screen. On ultra-wide monitors (for example 2560px), the extra space appears on both sides, while the header continues to stretch full width.
Grid spacing values (columns, gutters, margins) do not increase beyond the XL breakpoint.

The grid never becomes fluid beyond 1920px.

Breakpoint ≤ 1920



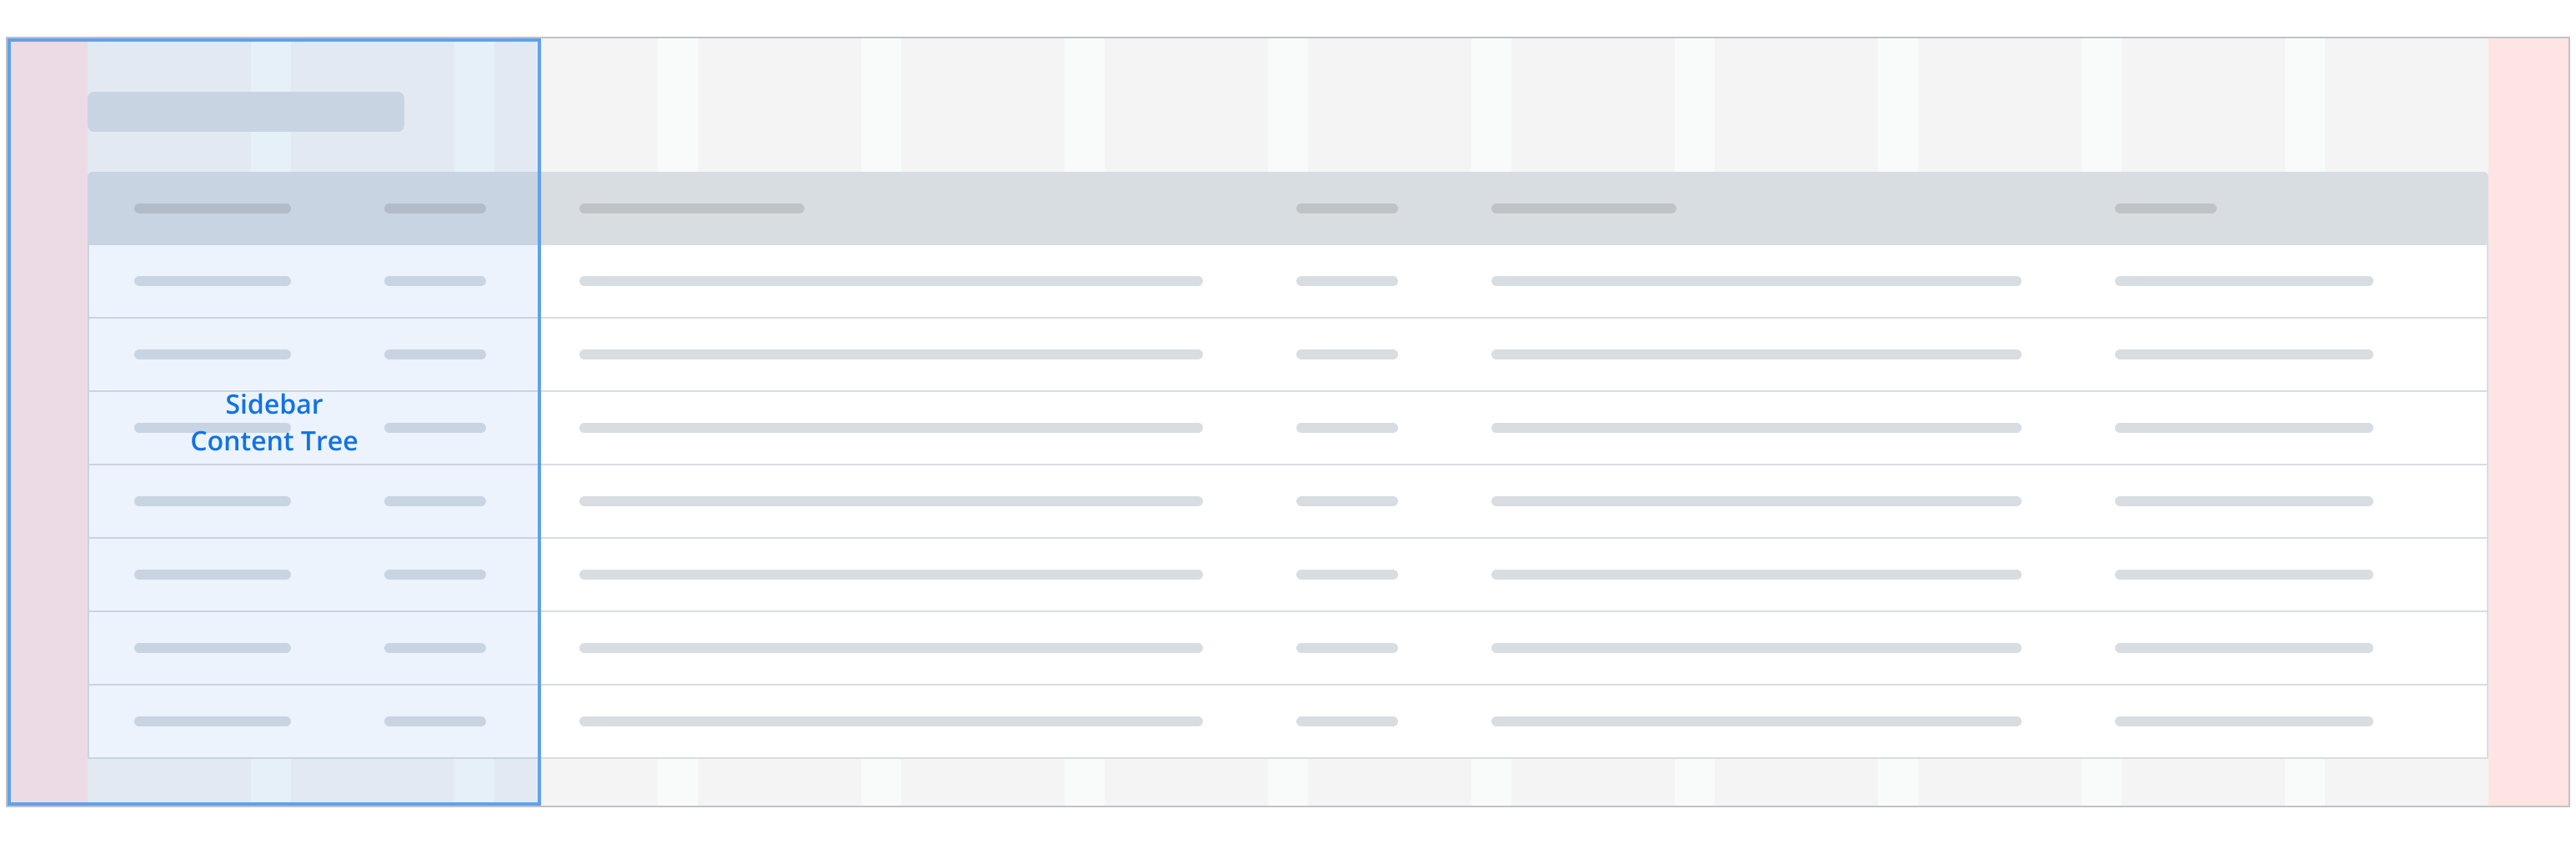
Breakpoint ≥ 1920



Side Panel Behavior

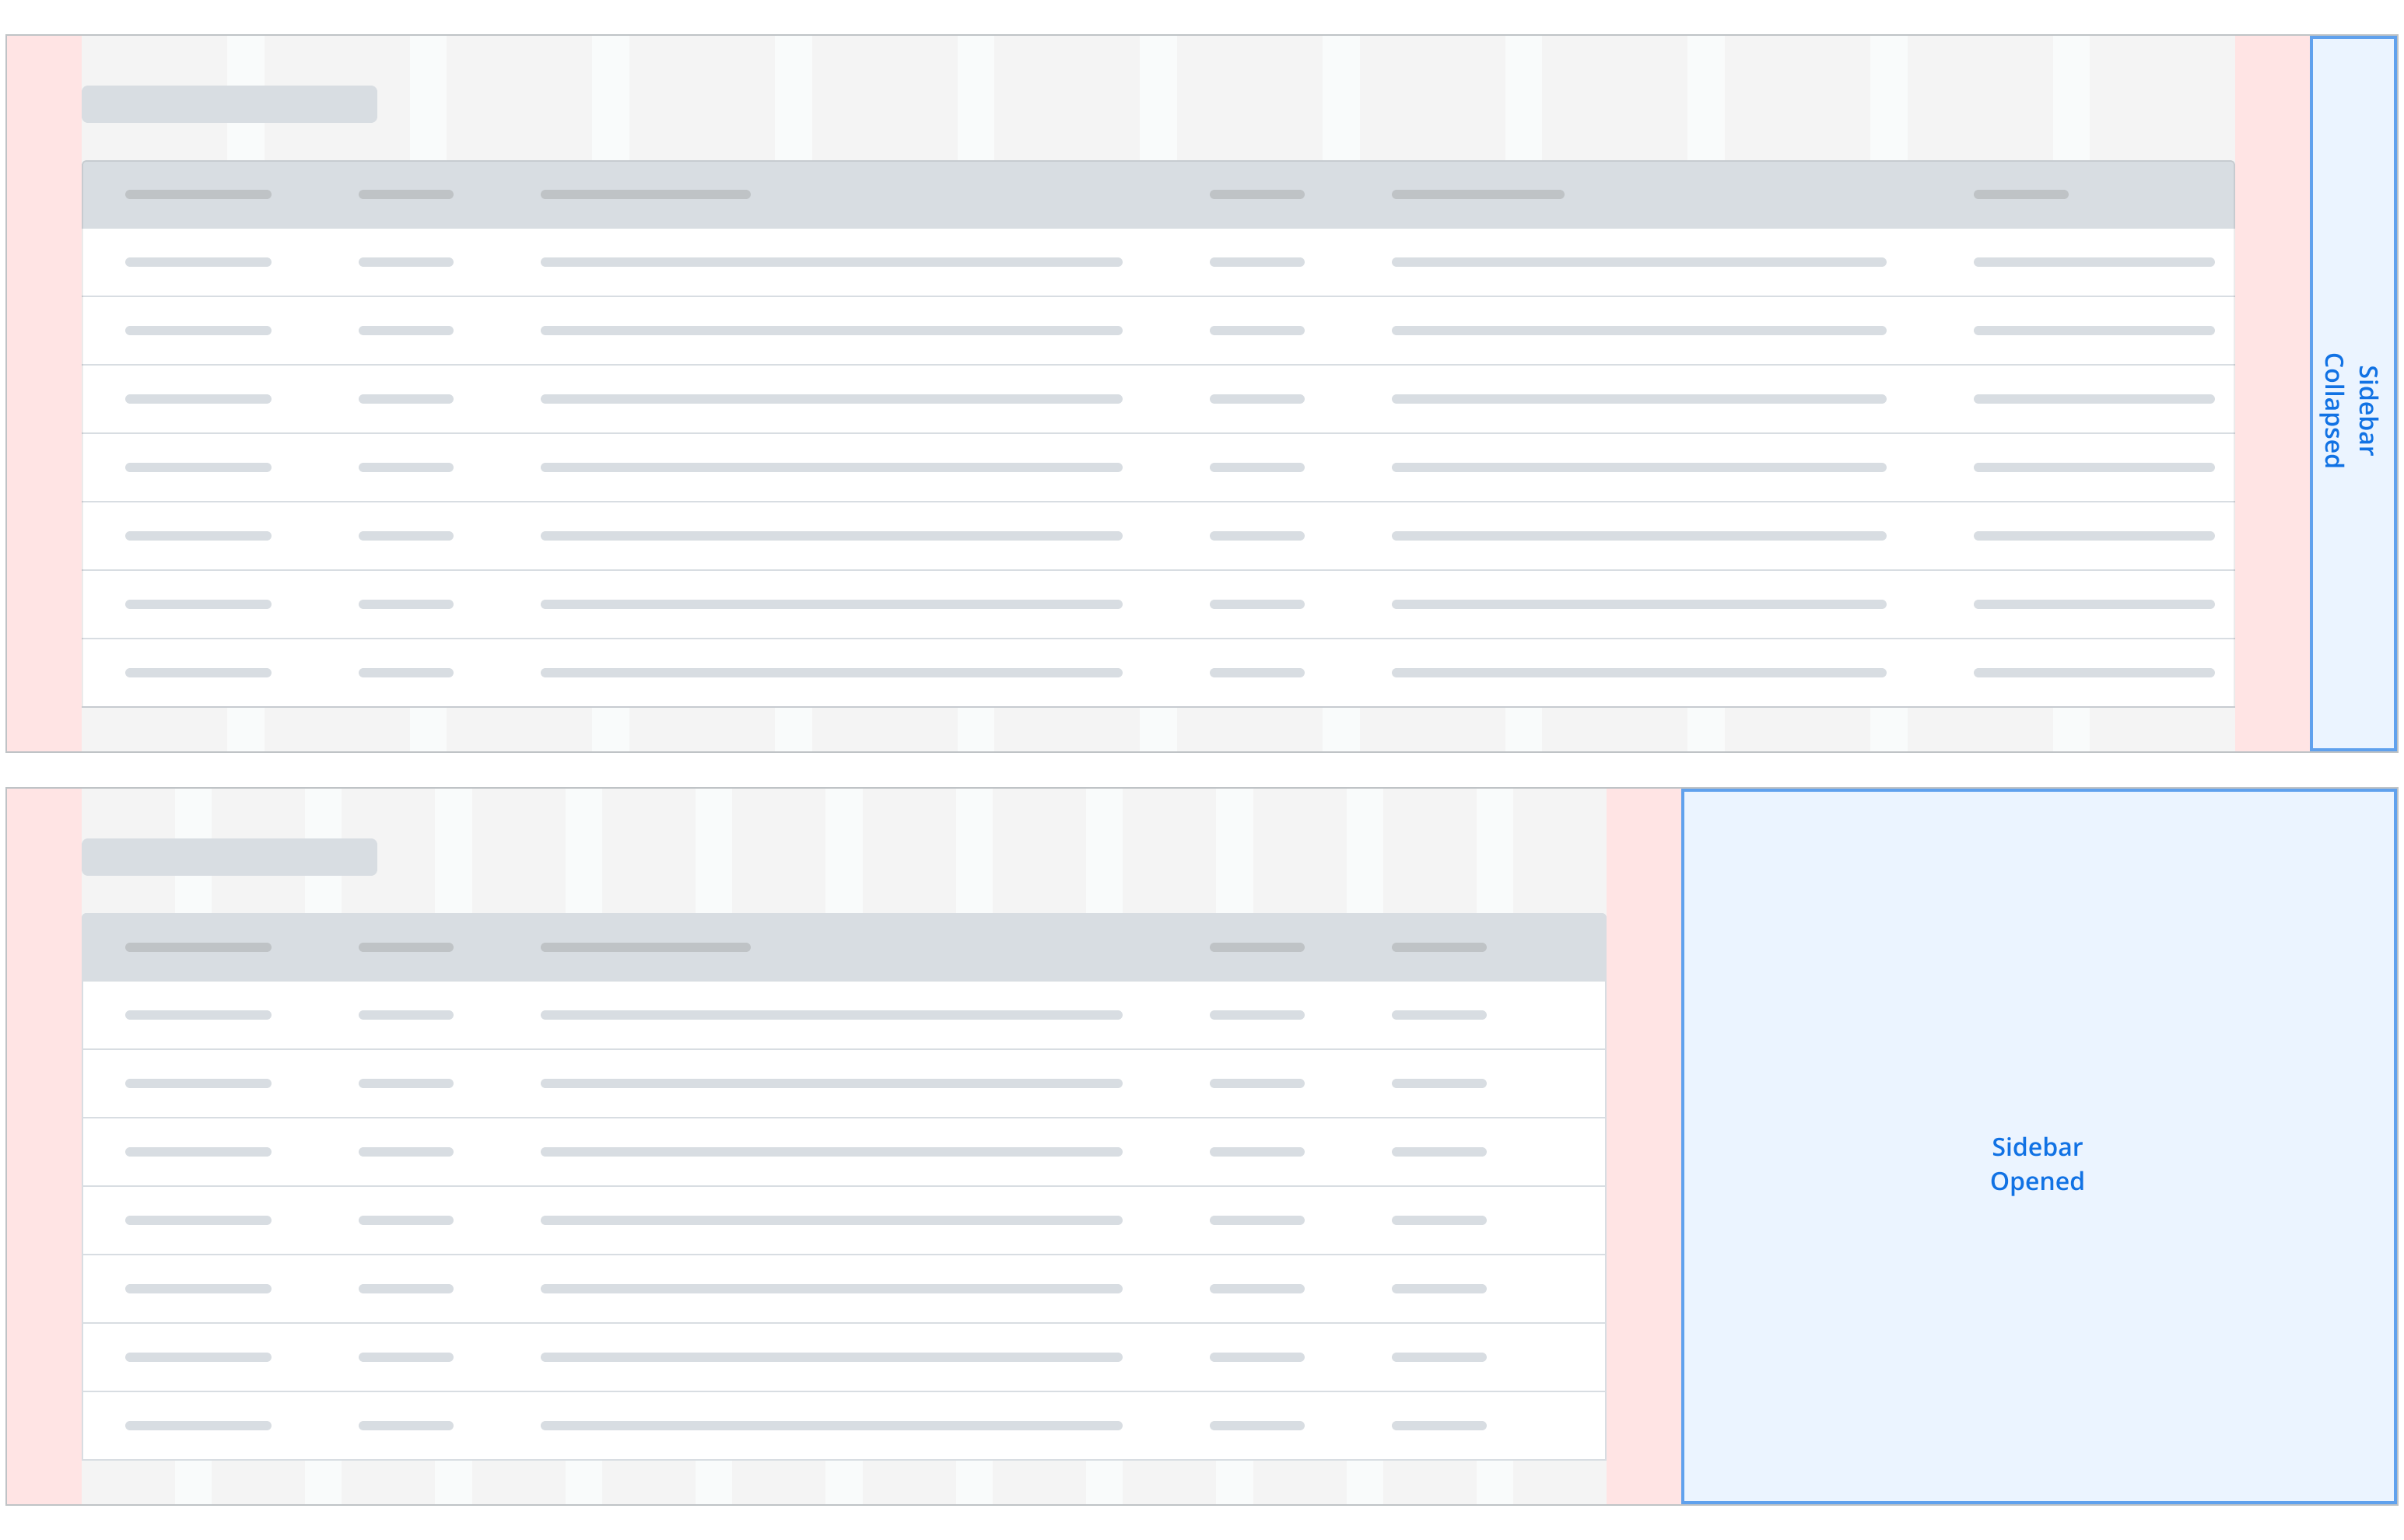
Left Browse Panel

The left panel is resizable between 235px and 460px and always opens as an overlay on top of the grid, so it does not reduce or recalculate the grid width.
On SM it still overlays the content. On XS it opens full-screen.



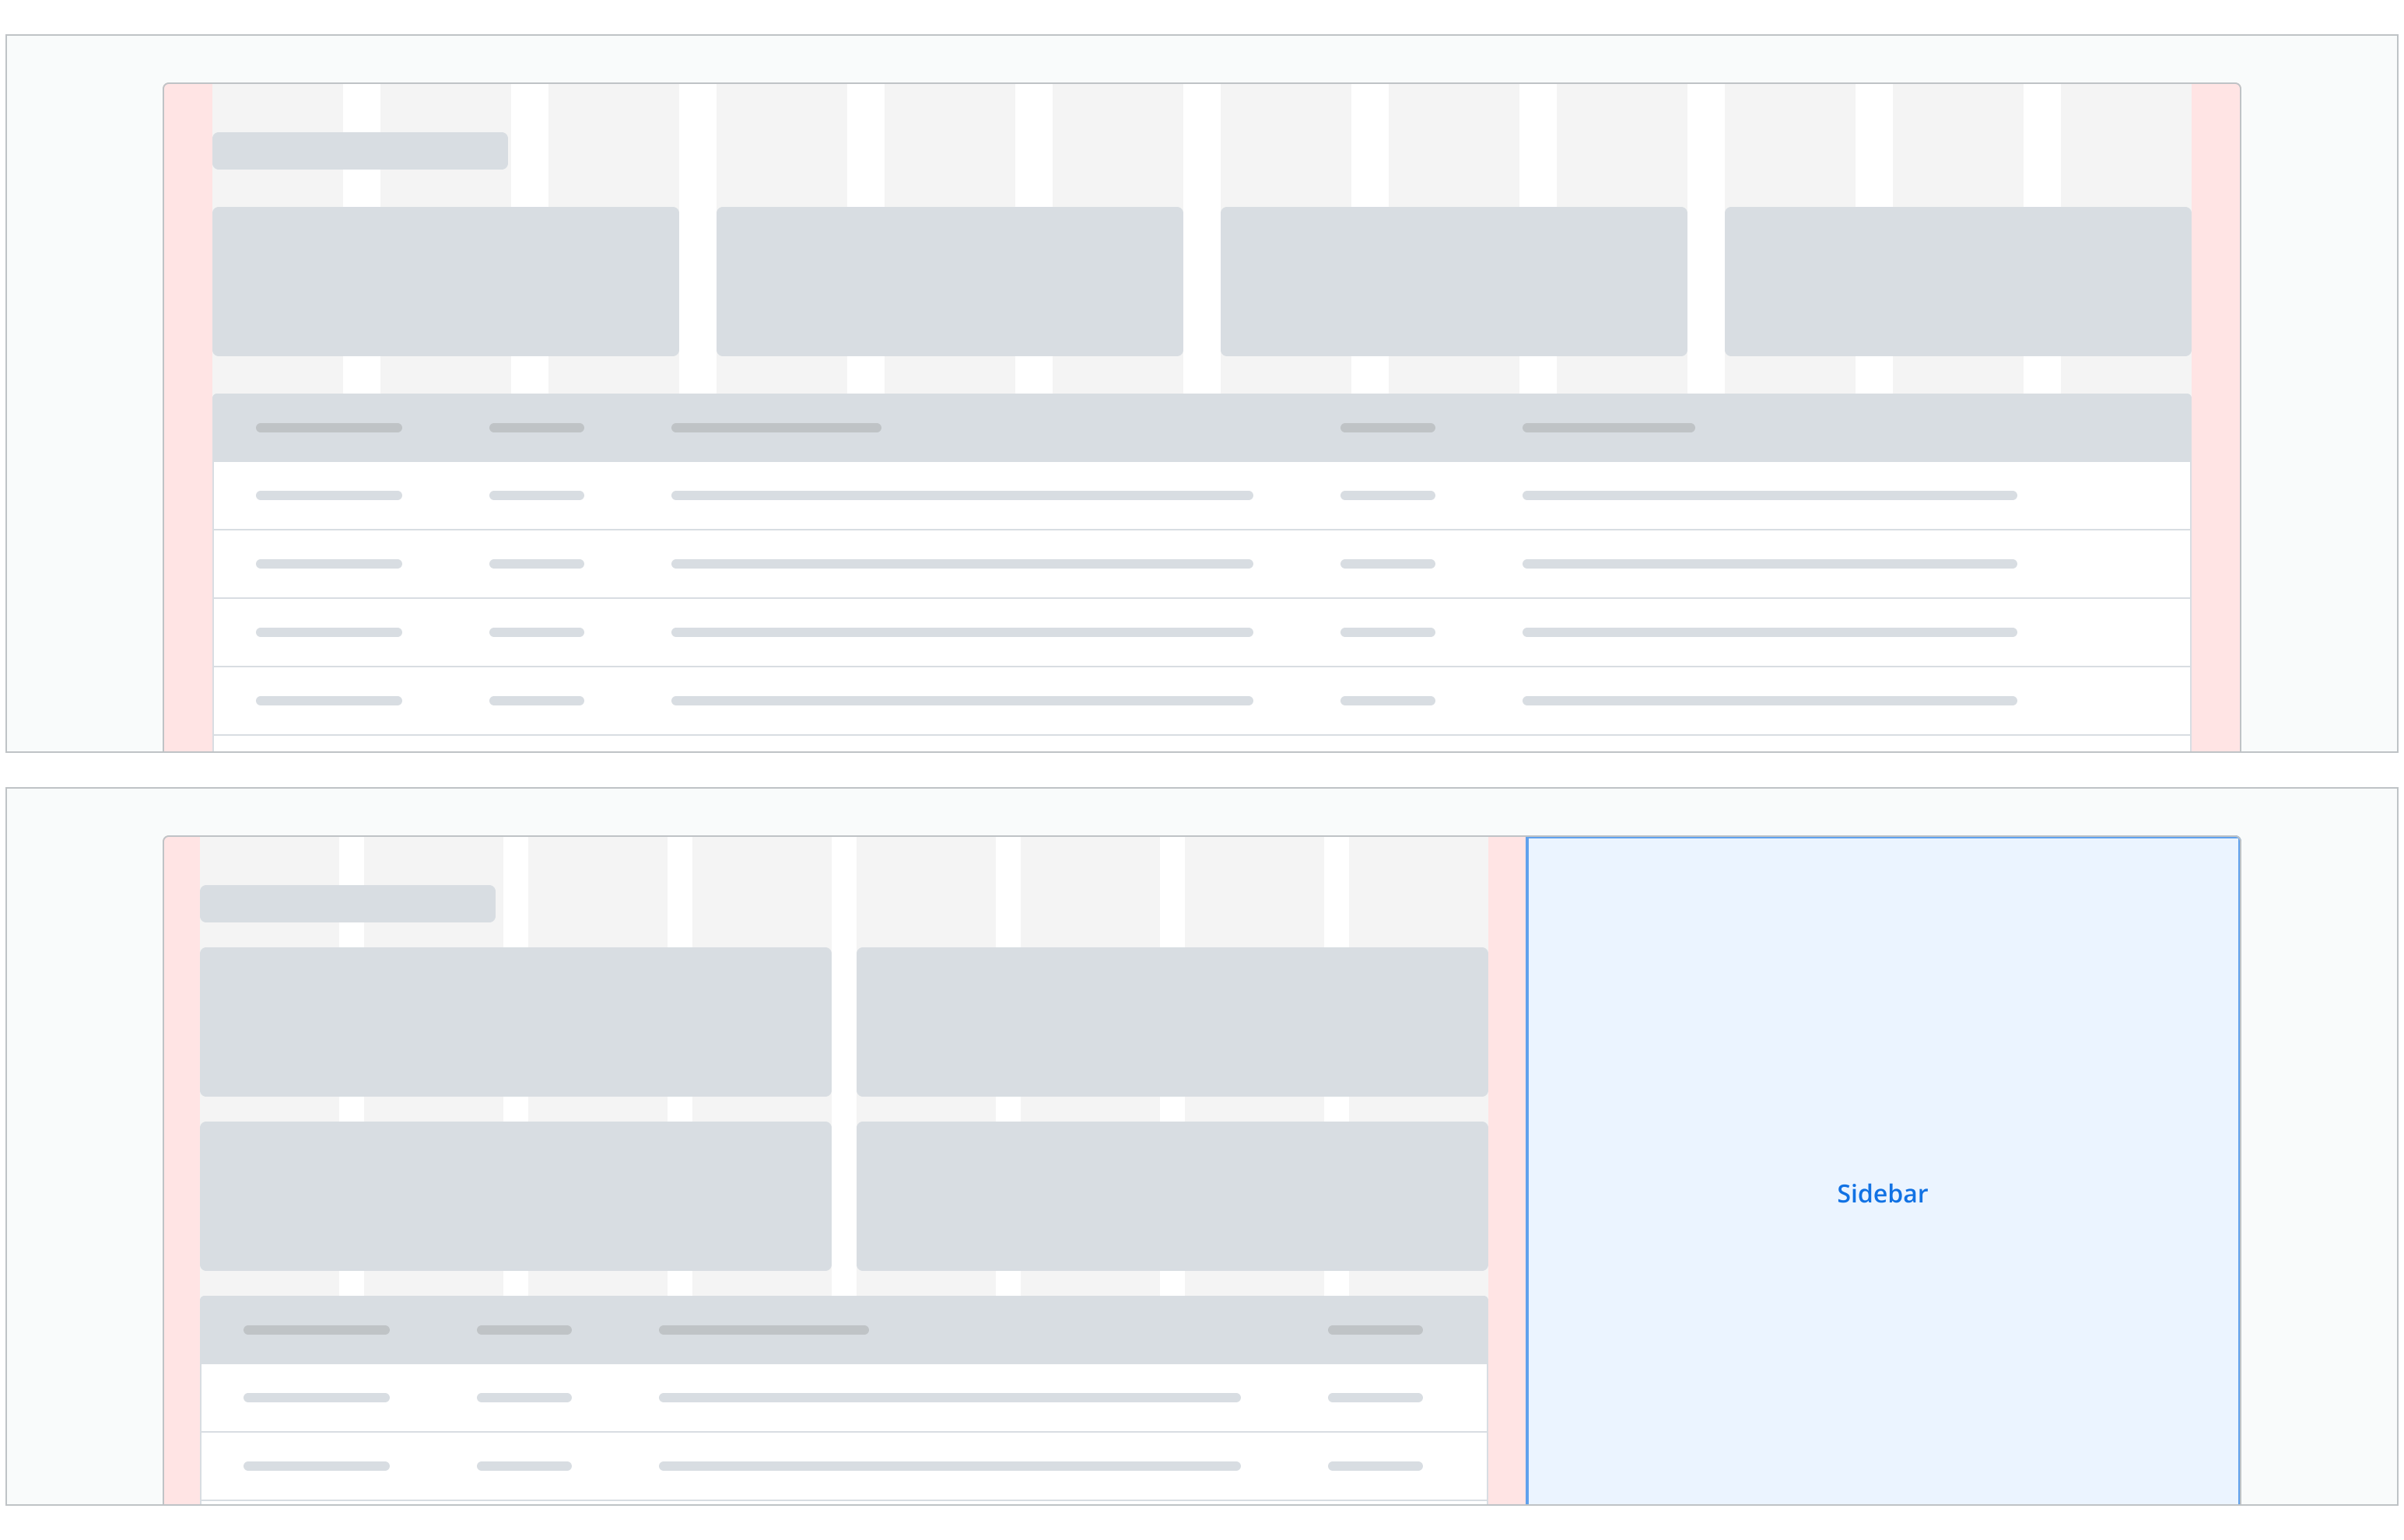
Right Article Panel

The right panel is not part of the grid system, but when it opens, it reduces the available width of the grid container. The grid itself does not change structure immediately — it keeps its column definition as long as there is enough space.
On desktop it has a fixed width of 460px (open) and 56px (collapsed). It is not part of the grid, but when it appears it reduces the available space for the grid container and the content inside it.
On MD it has 360px width.
On SM and XS, the right panel takes the whole screen width (tablet/mobile layout).



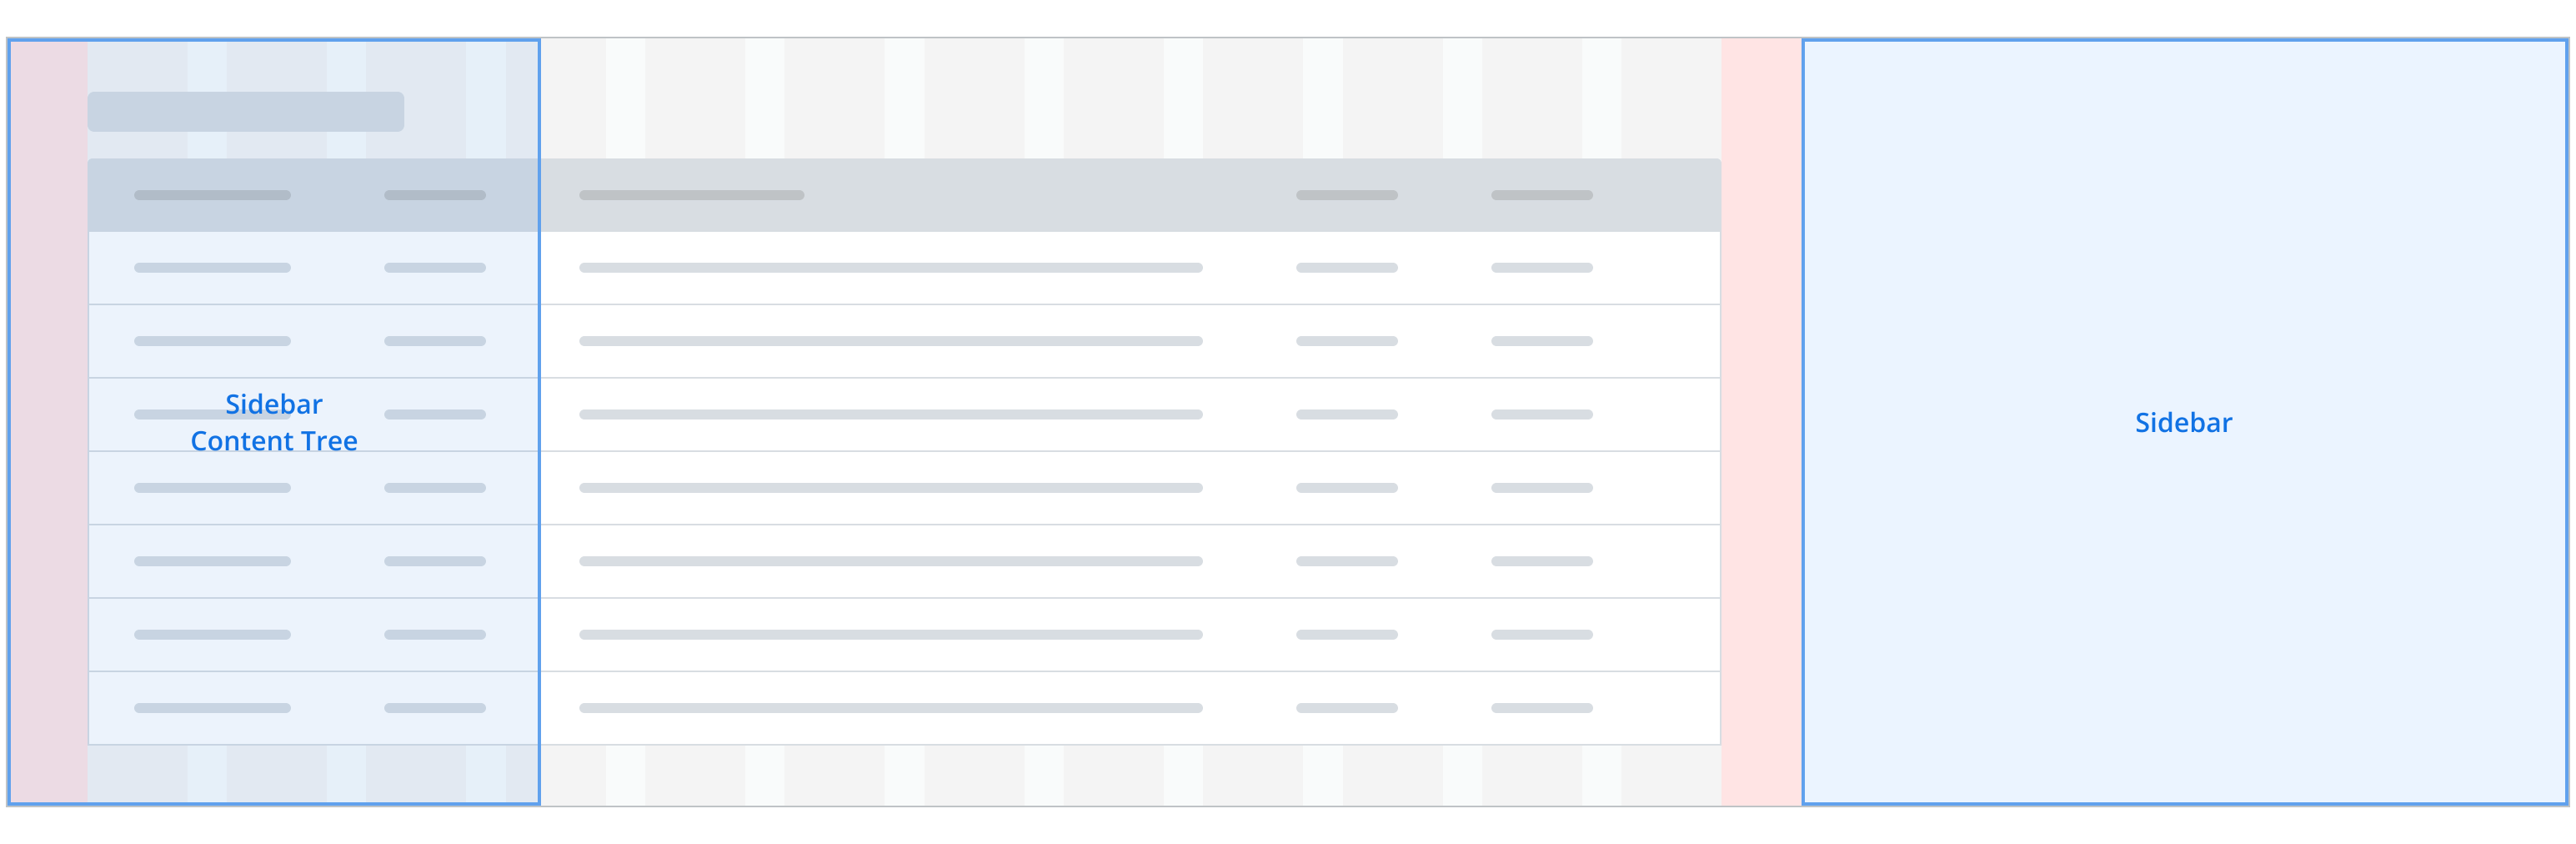
Right Article Panel - breakpoint changed

However, if opening the right panel causes the content width to become smaller than the current breakpoint range, the grid automatically shifts to the next appropriate breakpoint.



Dual Panel Layout

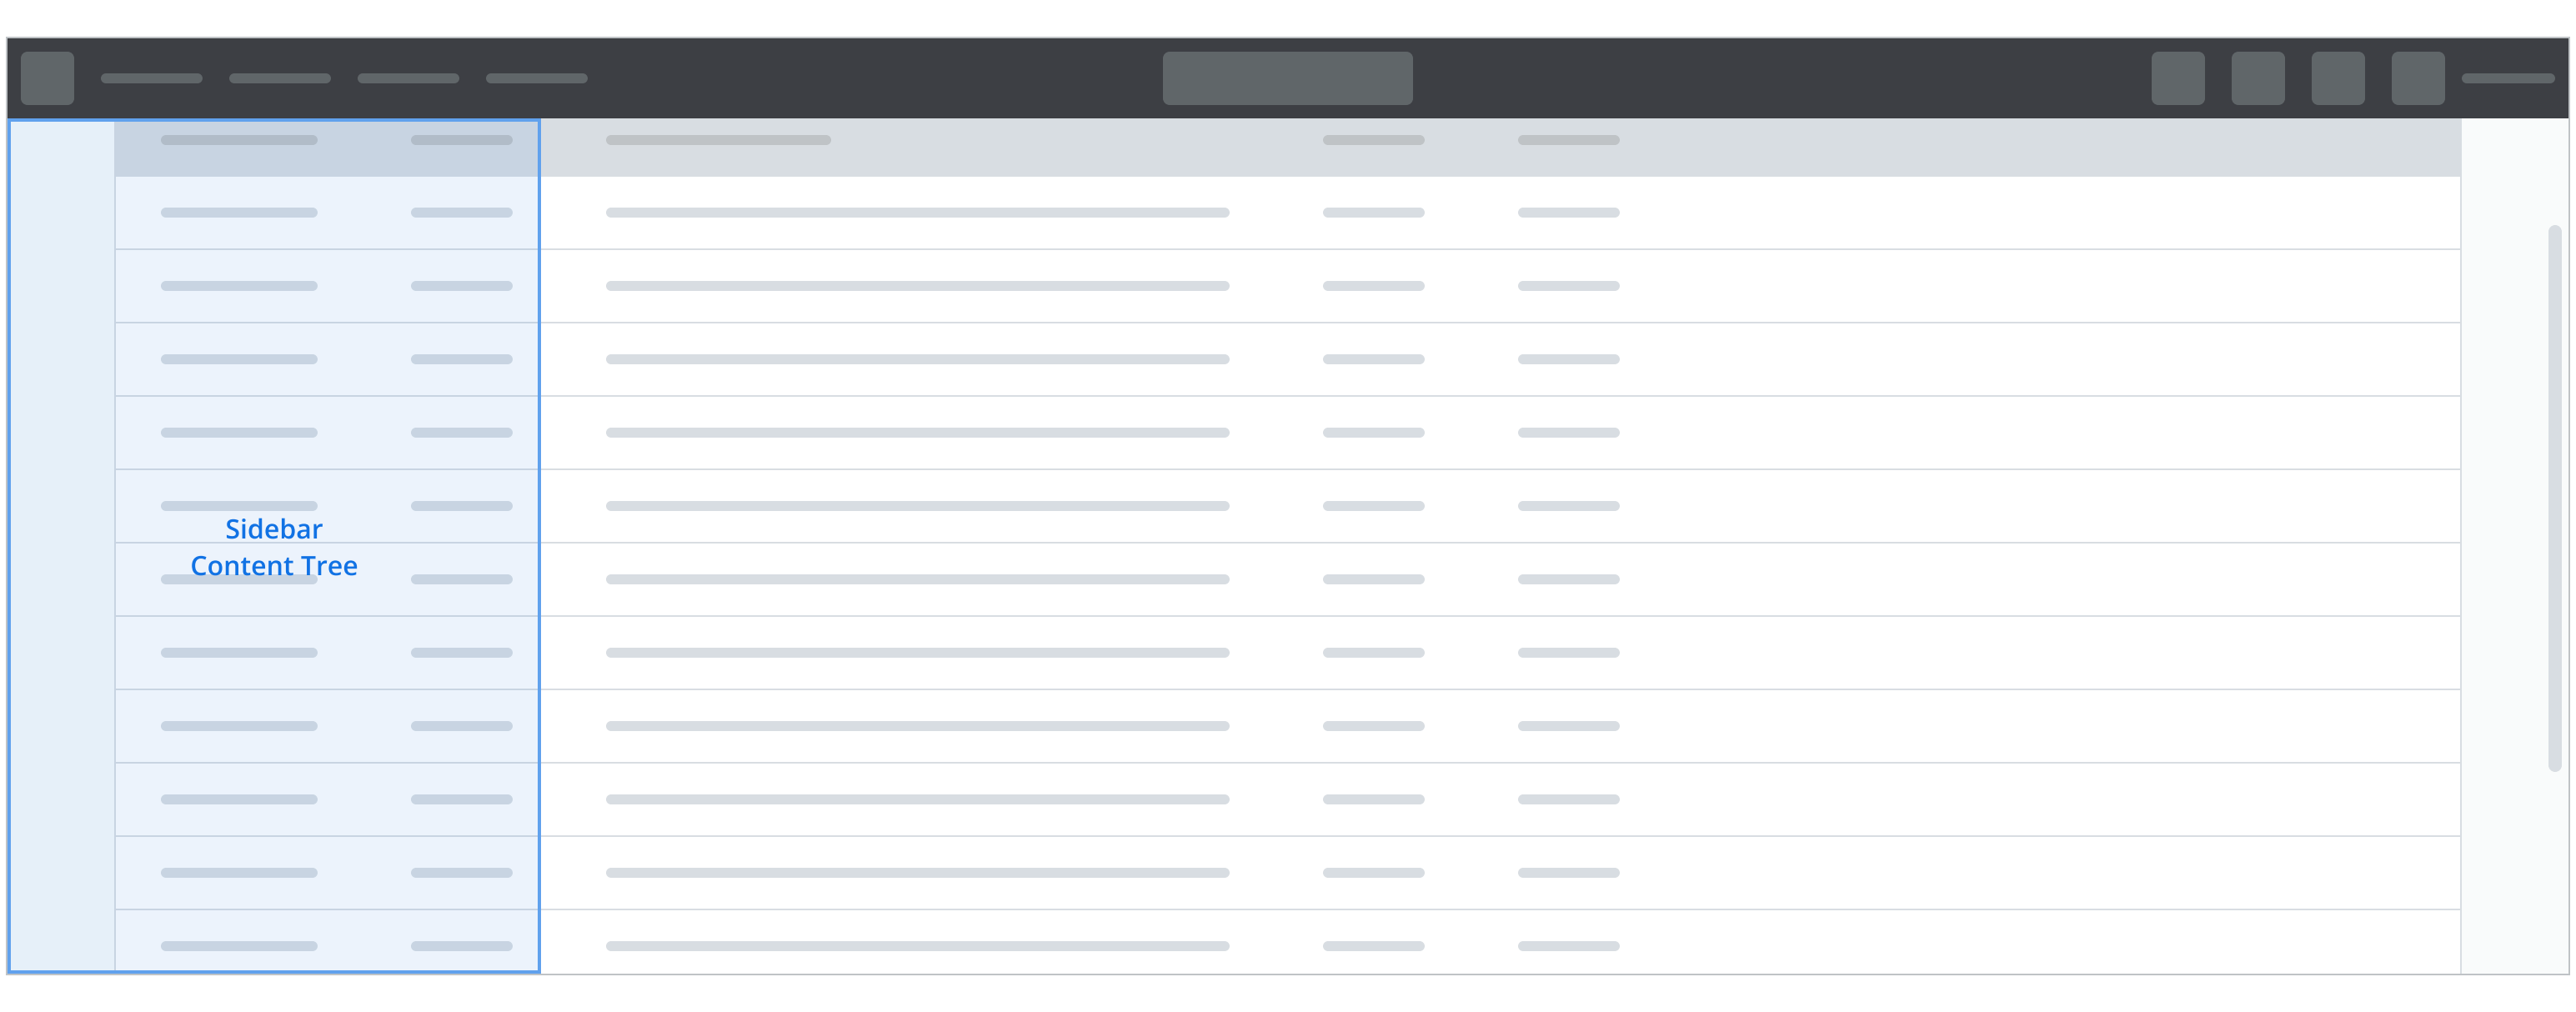
On large screens, both panels can be used at the same time. In this case, the left panel continues to overlay the grid, while the right panel reduces the grid container width. The layout should stay readable and stable, without creating horizontal page scrolling.



Scroll Behavior

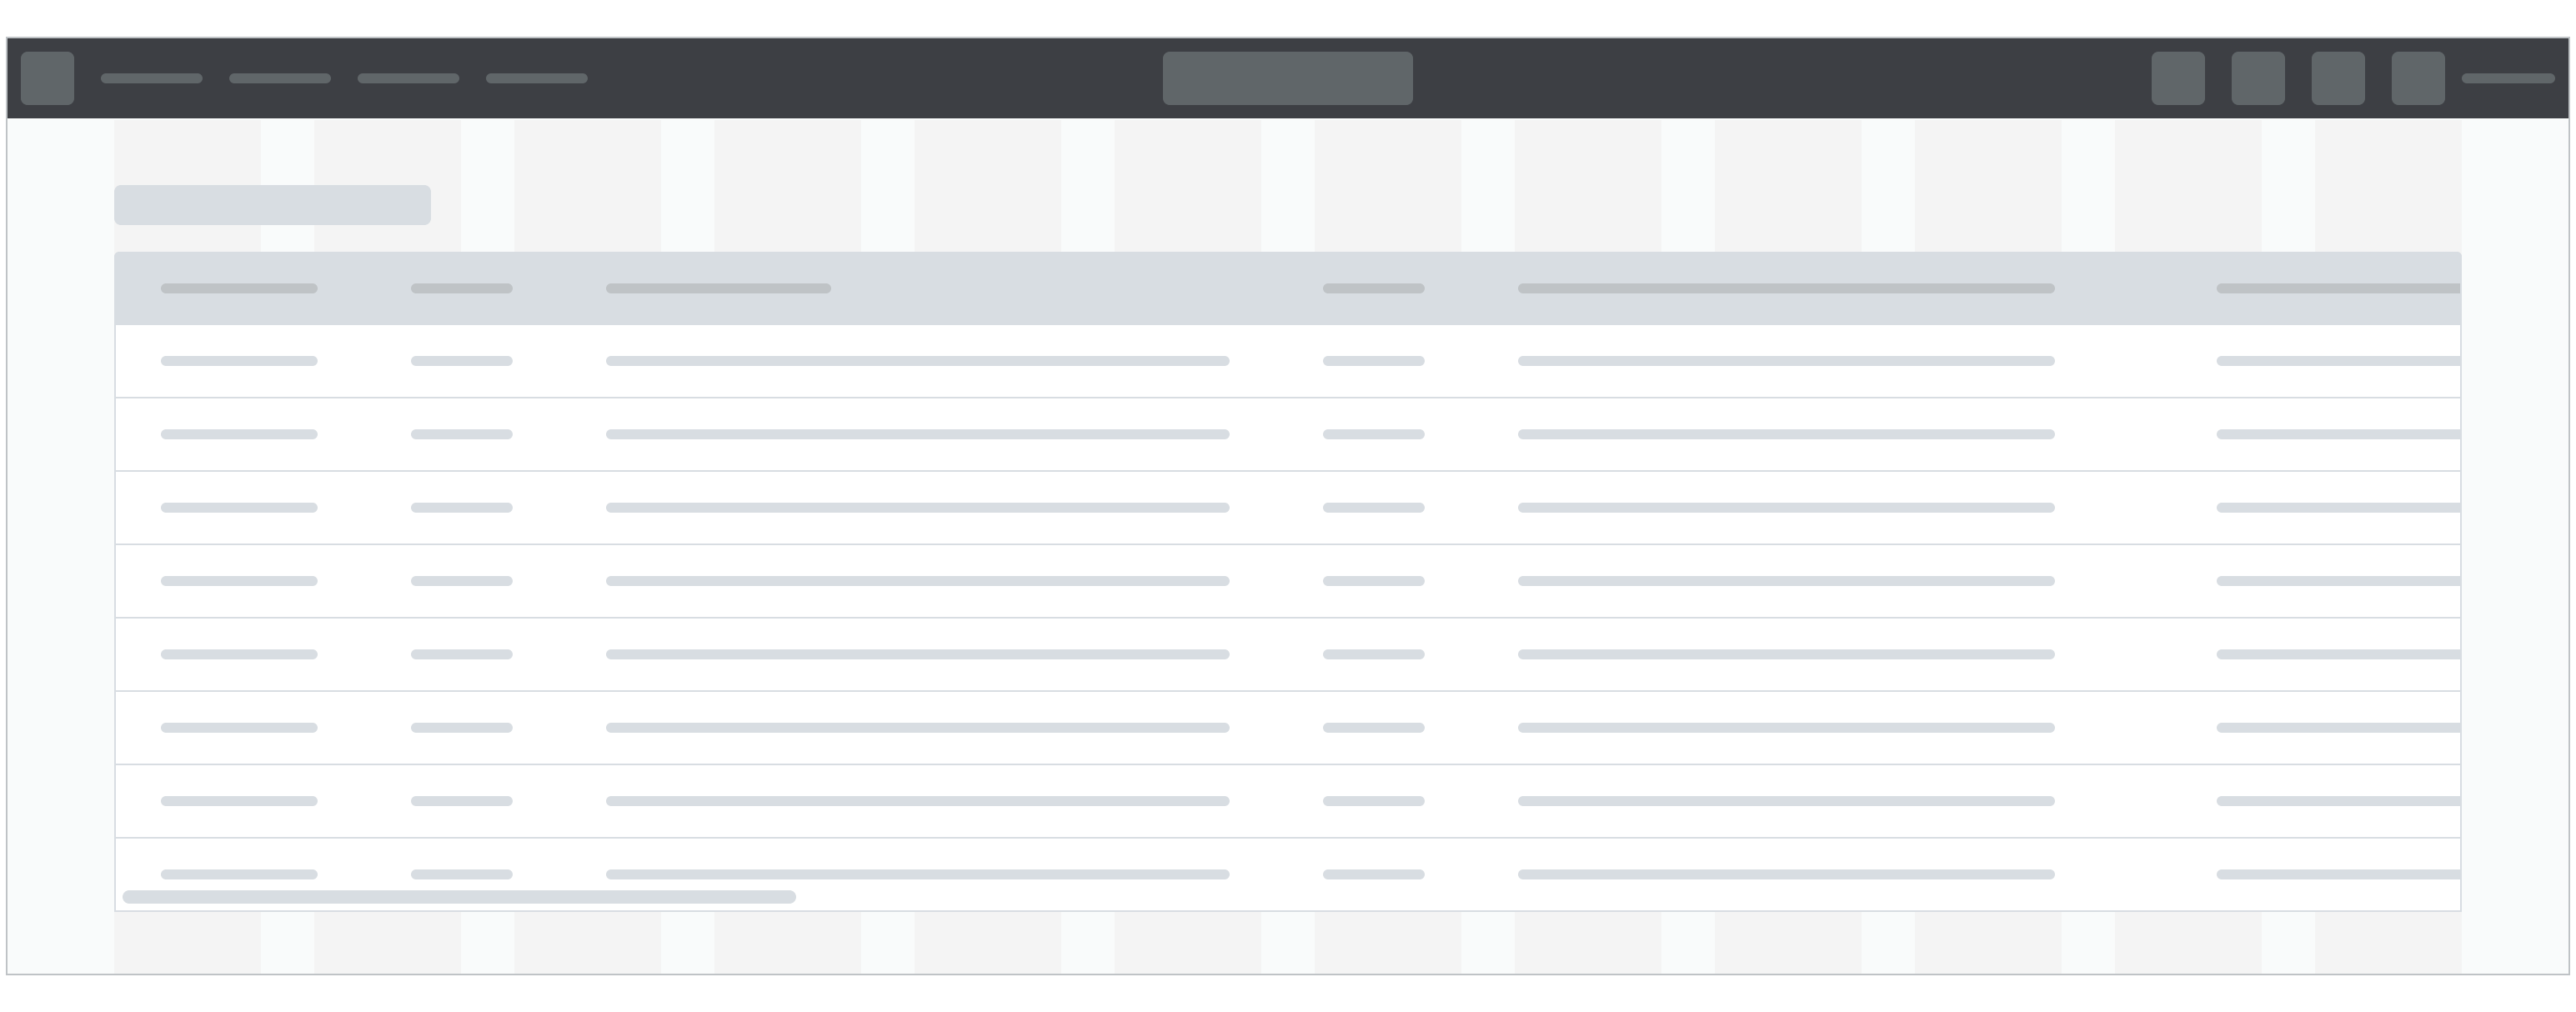
The header is sticky. Side panels are also sticky. The page scrolls vertically as usual.
Horizontal scrolling should happen only inside dedicated components (such as tables), not on the page level.

Vertical Scroll



Horizontal table Scroll

Tables take 100% of their container width. When tables have many columns, they scroll horizontally inside the table container. The page itself should not scroll horizontally.

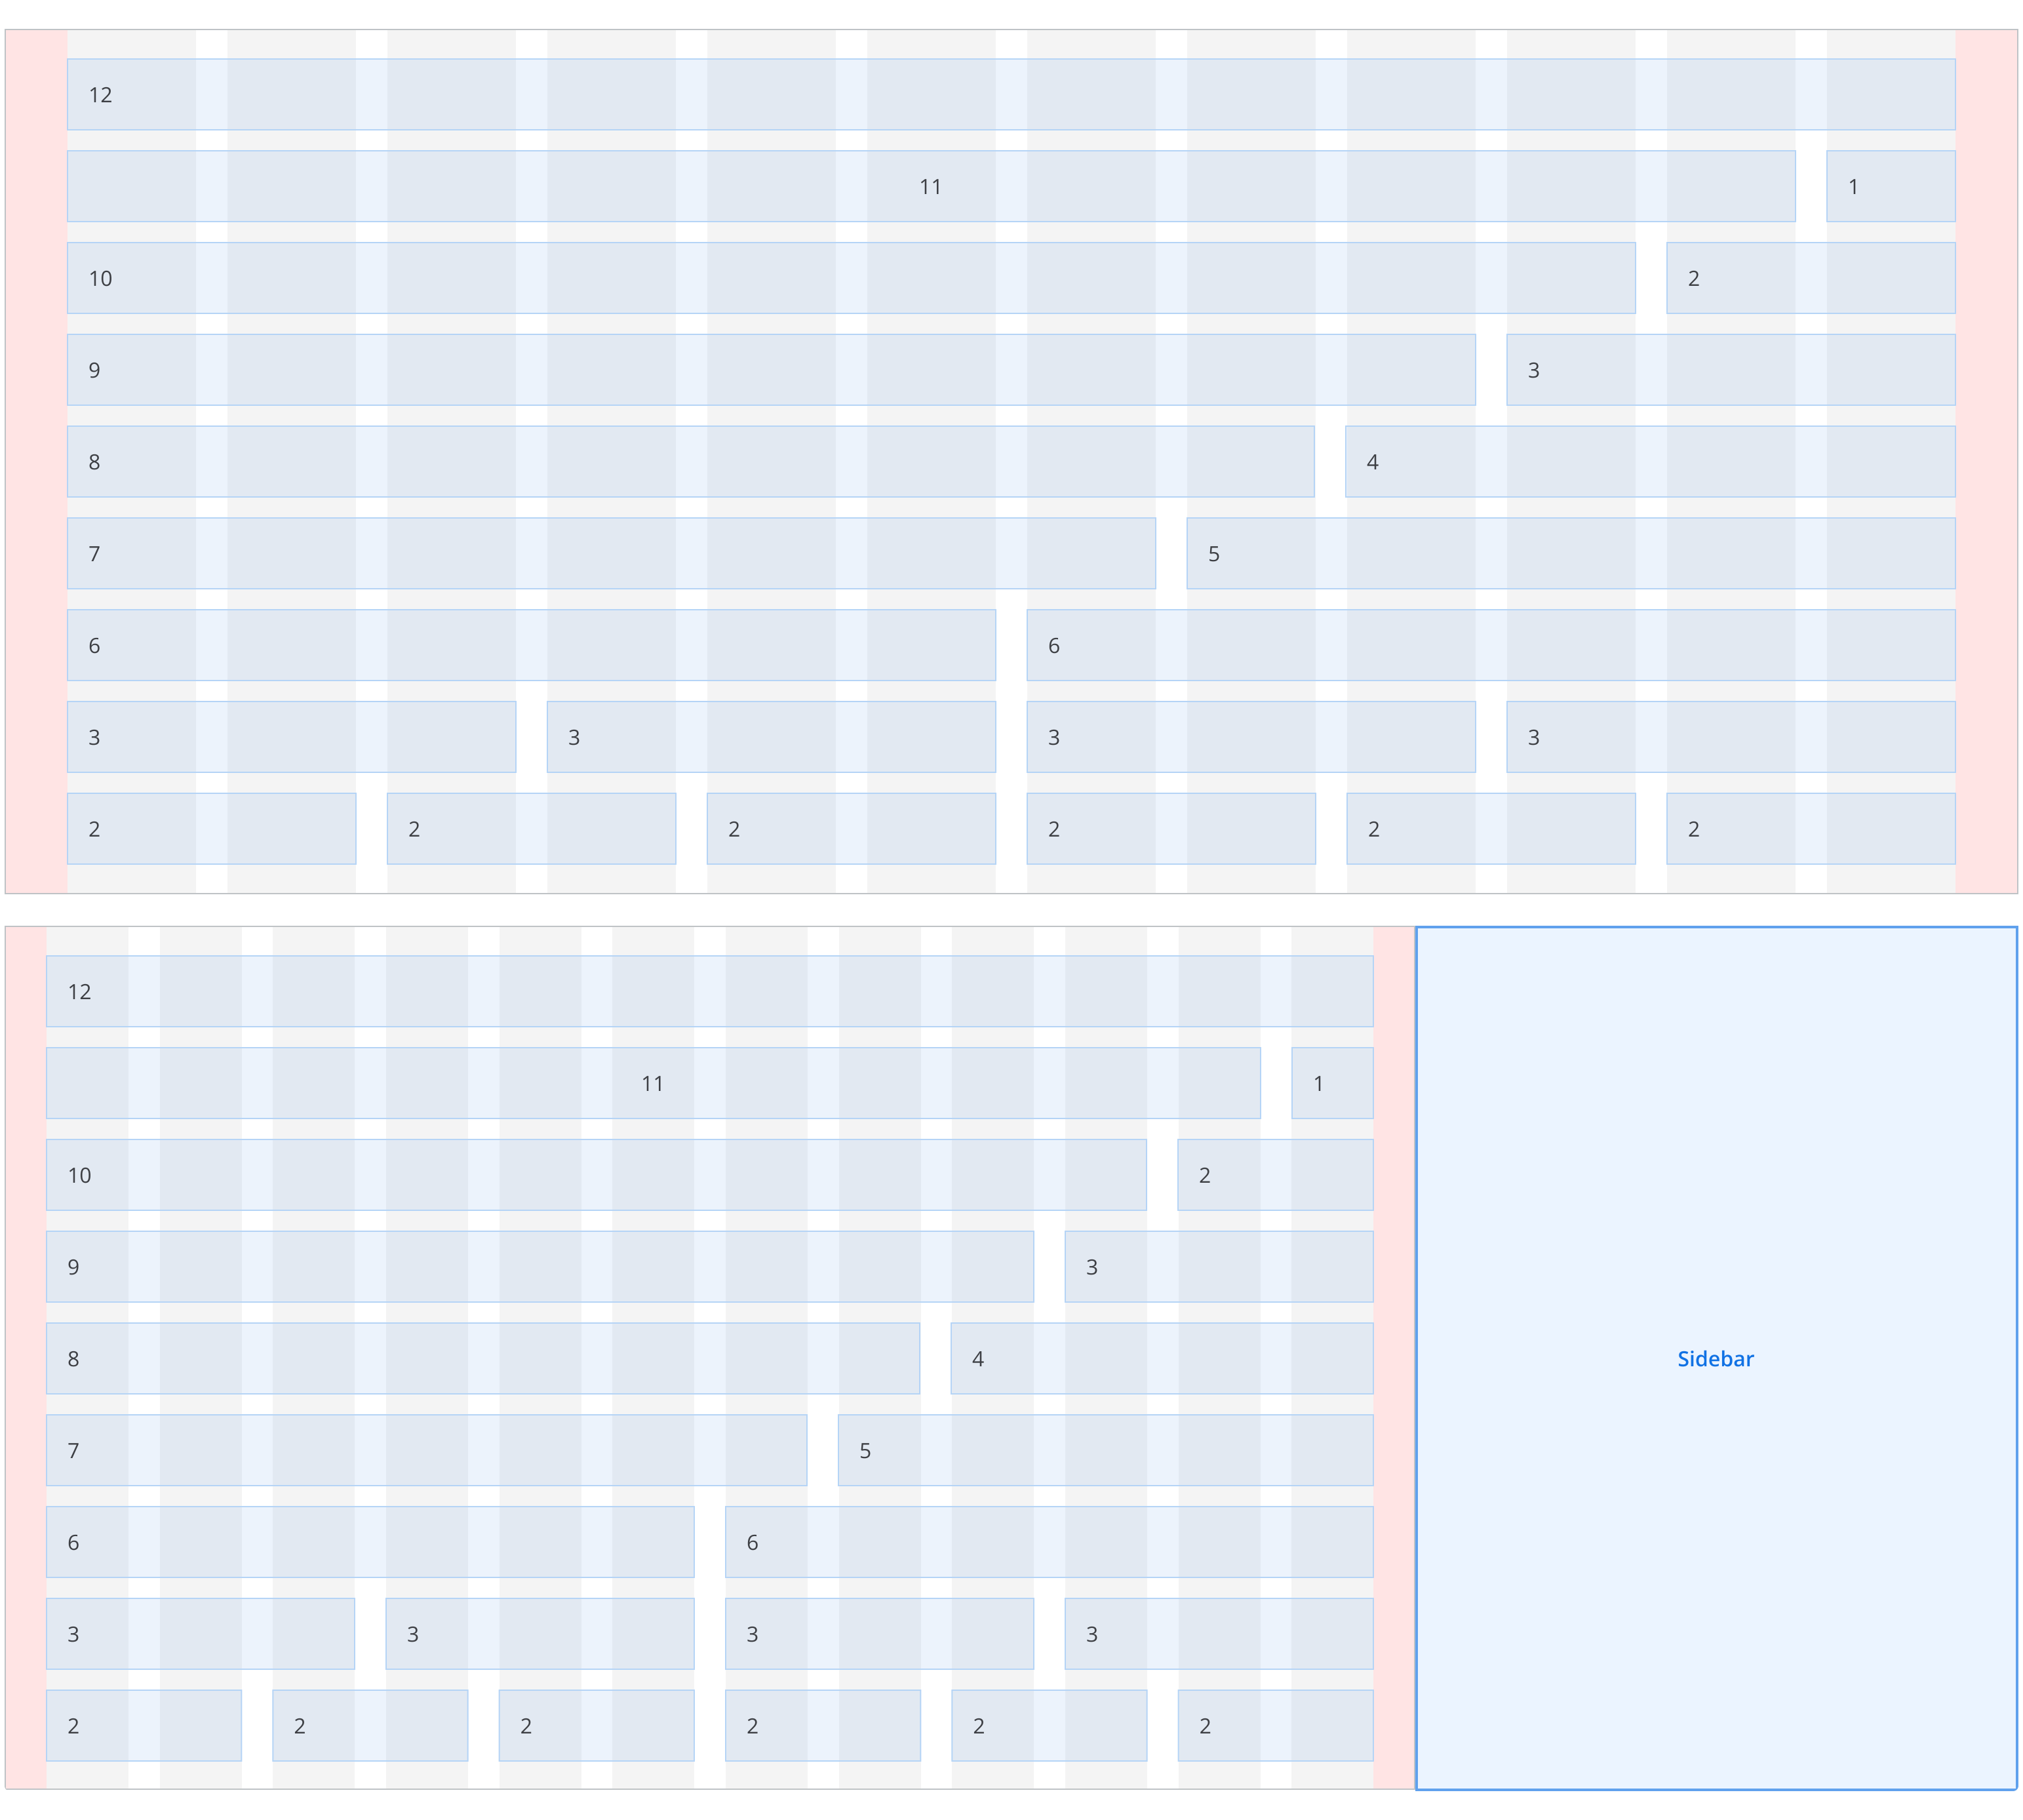


Grid Interaction Rules

The grid system defines alignment inside the main content container. Side panels are structural elements and do not belong to the grid.

The right panel reduces available content width. When this reduced width crosses a breakpoint threshold, the grid recalculates and switches to the corresponding breakpoint configuration. Column count, gutters, and margins follow the rules of the active breakpoint.

The grid should always respond to the effective content width, not the full viewport width.



Modal/Dialog Overlay Behavior

Modals cover the entire application, including the header. They sit above the grid and panels and block interaction with the background.
Modals do not affect grid calculations and should be treated as a separate overlay layer.
